Taxonomy and systematics

A new species of scorpion of the genus *Centruroides* (Scorpiones: Buthidae) from the state of Michoacán, Mexico

Una especie nueva de alacrán del género Centruroides (Scorpiones: Buthidae) del estado de Michoacán, México

Abstract

Centruroides ruana sp. nov. is described from Felipe Carrillo Puerto, from the Buenavista Municipality in the state of Michoacán, Mexico. The new species was compared with *C. balsasensis* Ponce-Saavedra & Francke, 2004, *C. infamatus* Koch, 1844, and *C. limpidus* (Karsch, 1879), which are both morphologically its closest relatives and geographically proximate. The description includes the male holotype, with 7 male and 8 female paratypes. A supplementary morphometric analysis is also presented allowing to distinguish the 4 species.

Resumen

Se describe *Centruroides ruana* sp. nov. de Felipe Carrillo Puerto, municipio de Buenavista en el estado de Michoacán, México. Se hace una comparación con las especies morfológica y geográficamente más cercanas: *C. balsasensis* Ponce-Saavedra y Francke, 2004, *C. infamatus* Koch, 1844 y *C. limpidus* (Karsch, 1879). La descripción incluye el macho holotipo, 7 machos y 8 hembras paratípos. Se presenta un análisis morfométrico que también permitió diferenciar las 4 especies.

Introduction

The family Buthidae is the most speciose in the order Scorpiones. It currently includes 91 genera and 1,044 species worldwide (Ponce-Saavedra & Francke, 2013a; Rein, 2015; Teruel, Kovarik, Baldazo-Monsivais, & Hoferek, 2015). In

Mexico, the family is represented by 2 genera: *Centruroides* Marx, 1890, with 42 species out of a total of 85 native to the American continent, and *Chaneke* Francke, Teruel and Santibañez-López, 2014, with 2 species (Francke, Teruel, & Santibañez-López, 2014; Ponce-Saavedra & Francke, 2013a; Rein, 2015; Teruel et al., 2015).

Centruroides occurs continuously across the American continent from central USA through western South America, including most of the archipelagos associated with continents, such as the West Indies and Galapagos. It is the most common and widespread scorpion genus in Mexico, and the only one that

Collection data of other *Centruroides* species and specimens that are morphologically similar to or from the same geographic region as *C. ruana* sp. nov. and used for the morphological and morphometric analyses.

Species	Locality/geographical coordinates	Number of individuals	
		♂♂	♀♀
<i>Centruroides balsasensis</i>	Arúa, Huetamo Michoacán, Mexico/18.540278N, 100.926389W	4	3
<i>Centruroides balsasensis</i>	Churumuco, Michoacán, Mexico/18.660833N, 101.646111W	3	4
<i>Centruroides infamatus</i>	León, Guanajuato, Mexico/21.017222N, 101.628889W	3	2
<i>Centruroides infamatus</i>	Zumpimito, Uruapan, Michoacán, Mexico/21.125000N, 101.030278W	4	4
<i>Centruroides limpidus</i>	Arcelia, Guerrero, Mexico/18.283056N, 100.266667W	7	7
<i>Centruroides tecomanus</i>	Faro de Bucerías, Aquila, Michoacán, Mexico/18.335833N, 103.500833W	7	6

has medical importance due to the toxicity of several species (Fet & Lowe, 2000). Recent contributions (Ponce-Saavedra & Francke, 2013a,b; Ponce-Saavedra, Martínez-Rodríguez, & Quijano-Ravell, 2015) list 7 species of *Centruroides* for the state of Michoacán, with well-defined geographical distributions: (1) Balsas Basin (locally known as “tierra caliente”, a vernacular term that literally means “hot lands”): *Centruroides balsasensis* Ponce-Saavedra & Francke, 2004, *Centruroides bertholdii* (Thorell, 1876), *Centruroides infamatus* (C. L. Koch, 1844), and *Centruroides limpidus* (Karsch, 1879). (2) Pacific coastal plain: *Centruroides nigrescens* (Pocock, 1898) and *Centruroides tecomanus* Hoffmann, 1932. (3) Transverse Volcanic Belt: *Centruroides ornatus* Pocock, 1902.

The Balsas Basin is a unique biogeographical region of Mexico evidenced by high levels of plant and animal endemism. In the case of scorpions, 2 genera are endemic: *Kuarapu* Francke and Ponce-Saavedra, 2010 and *Balsateres* González-Santillán and Prendini, 2013. Also, 6 species are restricted to this basin: the diplocentrids *Diplocentrus churumuco* Francke and Ponce-Saavedra, 2004 and *Kolotl poncei* (Francke and Quijano-Ravell, 2009); the vaejovids *Balsateres cisnerosi* (Ponce-Saavedra and Sissom, 2004), *Konetontli kuarapu* (Francke and Ponce-Saavedra, 2006), and *Kuarapu purhepecha* Francke and Ponce-Saavedra, 2010; and the buthid *Centruroides balsasensis* Ponce-Saavedra & Francke, 2004.

The new species described herein represents yet another case of an endemic scorpion from the Balsas Basin and increases the number of *Centruroides* known to occur in Michoacán and the Balsas Basin to 8 and 5, respectively.

Materials and methods

Scorpions were collected during daytime by intensive direct sampling, i.e., turning rocks and other objects on the ground, peeling bark, and searching inside soil cracks and crevices. All specimens were preserved in 96% ethanol. They were deposited in the following collections: holotype and some paratypes at the Colección Nacional de Arácnidos, Instituto de Biología, Universidad Nacional Autónoma de México, D.F., Mexico (CNAN), and paratypes at the Colección Aracnológica del Laboratorio de Entomología “Biol. Sócrates Cisneros Paz”, Facultad de Biología, Universidad Michoacana de San Nicolás de Hidalgo, Morelia, Michoacán, Mexico (CAFBUM).

The specimens were studied, measured and photographed using a Zeiss Stemi DV4 stereomicroscope, equipped with a 0.1 mm ocular micrometer. High-resolution digital photographs were taken using either white or UV light and then slightly processed with Adobe Photoshop CS5, only to remove background and to optimize brightness and contrast parameters for printing. Measurements and pectinal tooth counts were taken to analyze morphometric and meristic variation of the species. All measurements are reported in millimeters (mm). The description was made according to nomenclature and measurements of Stahnke (1970), except for the description of carination of the chelae of pedipalp, which was made according to Acosta, Candido, Buckup, and Brescovit (2008) and the carination of metasomal segments, which followed Francke (1977).

A direct morphological comparison was made among adults of similar species from samples taken in different localities of Mexico, including material coming from the type locality of *C. balsasensis* and specimens of *C. limpidus*, from Arcelia, Guerrero, and *C. infamatus*, from León, Guanajuato and from Uruapan, Michoacán. These 3 species are morphologically the most similar to the new species. Further, samples of *C. tecomanus* from Faro de Bucerías, Aquila, Michoacán, were also included in the comparison because this species can also be confused if the color pattern of the carapace is not considered (Table 1).

To determine which variables were best to diagnose the new species, a morphometric comparison was conducted based on 54 variables: 28 direct measurements, 25 calculated proportional ratios, and pectinal tooth counts (Table 2). Some of these ratios have been confirmed elsewhere as useful in other species of *Centruroides* (Ponce-Saavedra & Francke, 2004, 2009, 2011a, 2011b; Ponce-Saavedra, Francke, Cano-Camacho, & Hernández-Calderón, 2009; Santibáñez-López & Ponce-Saavedra, 2009).

The matrix generated was separated by sex, taking into account the well-known sexual dimorphism in most species of the genus (Hoffmann, 1932; Ozkan, Adiguzel, & Kar, 2006; Ponce-Saavedra & Francke, 2011a,b). A Multiple Correlation Analysis was run on each matrix, searching for both redundant (correlation $\geq 80\%$) and outlier data. In addition, a Principal Component Analysis (PCA) was applied to the data matrices, in order to detect the most informative variables to characterize species, e.g., a “noise-reduction filter” (unexplained

Diagnosis

This genus can be distinguished from all other members of Buthidae by the following combination of characters: (a) pedipalp fingers with 7–10 principal rows of denticles which are only slightly overlapping, oblique and flanked by external and internal supernumerary denticles on each side (missing in first and second instar immatures); (b) absence of stridulatory organ on sternite III and pectines; adult males with metasomal segments longer and narrower than females (Armas, 2009).

Centruroides ruana sp. nov.

(Morphometric data: Tables 2 and 3; Figs. 1–3 and 6–8)

Diagnosis

The species is distinguished by the combination of the following characters: Scorpions of medium to moderately large adult size (including telson) for the genus. *C. ruana* sp. nov. is a typical “striped scorpion”, basically yellow to ochre, paler ventrally, with 2 dorsal longitudinal blackish stripes on the mesosoma,

Figure 1. Habitus of dorsal and ventral views of holotype male and paratype female of *Centruroides ruana* sp. nov. Bars = 10 mm.

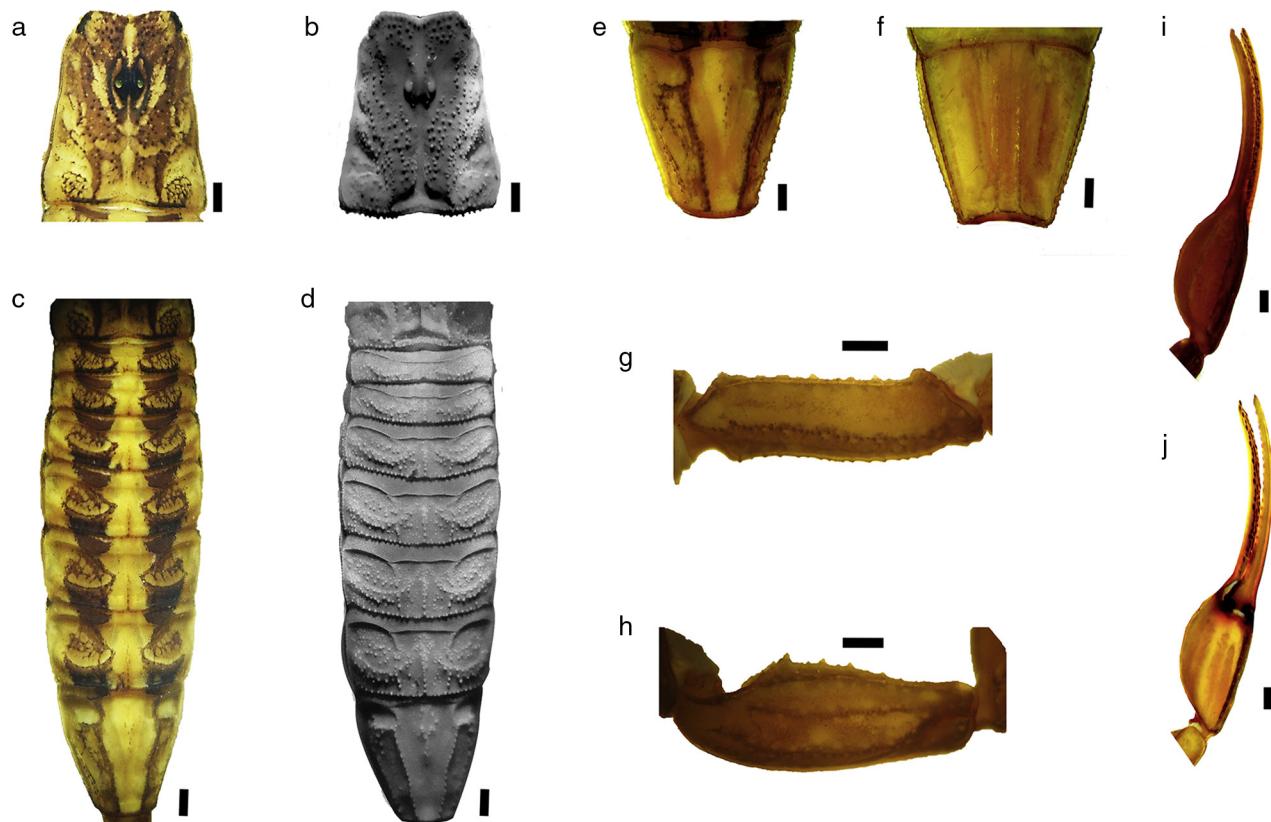

Figure 2. Adult male paratype of *Centruroides ruana* sp. nov.: (a and b) carapace; (c and d) mesosoma dorsal; (e) tergite VII; (f) sternite VII; (g) pedipalp femur dorsal; (h) pedipalp patella dorsal; (i) pedipalp chela, dorsoexternal view; (j) pedipalp chela ventrointernal view. Notes: photographs (a) and (b) were taken under UV light to show granulation. Bars = 1 mm.

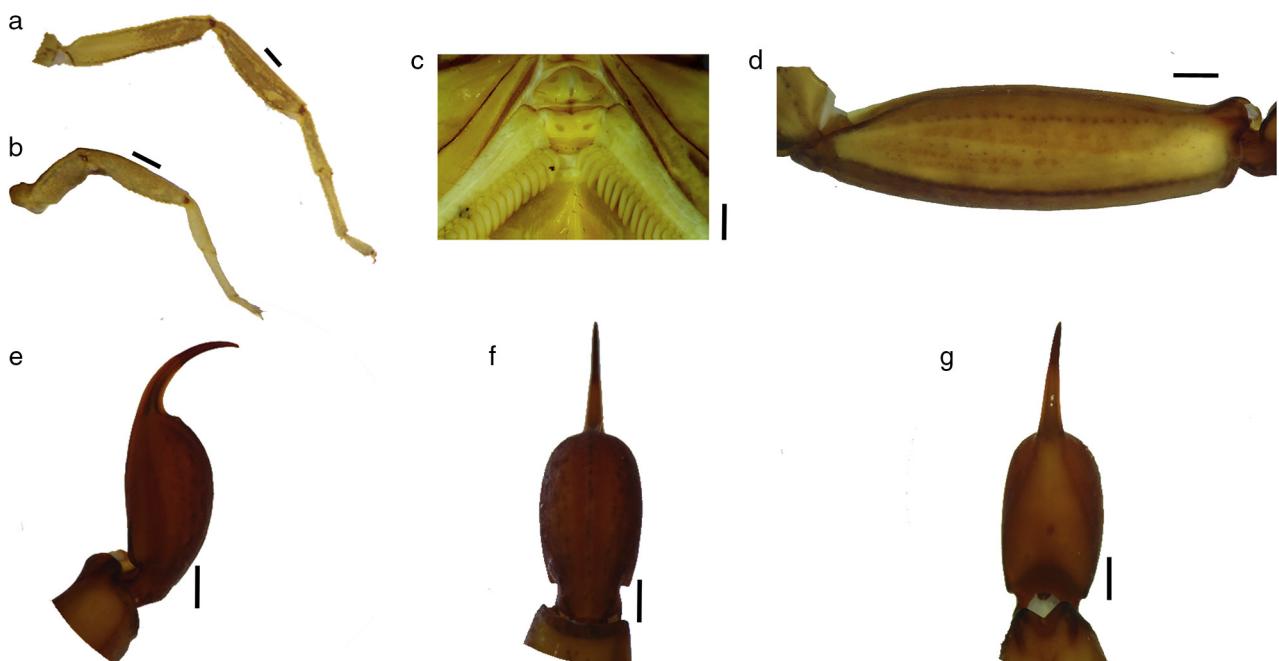

Figure 3. Adult male paratype of *Centruroides ruana* sp. nov.: (a) pigmentation leg IV; (b) pigmentation leg I; (c) basal pectinal plate; (d) metasomal segment V lateral; (e) telson lateral view; (f) telson ventral view; (g) telson dorsal view. Bars = 1 mm.

Figure 4. Sexual dimorphism in females *Centruroides ruana* sp. nov.: (a) tergite VII; (b) pedipalp chela dorsal view; (c) pedipalp chela ventral view; (d) basal pectinal plate; (e) metasomal segment V, lateral view; (f) telson, lateral view. Bars = 1 mm.

separated by a slightly wider pale stripe. Anterior median area of the carapace strongly pigmented in the anterior half except in the anterior median furrow and 2 areas above the lateral central furrow; the rear half area is slightly dark pigmented on both sides of the posterior median furrow and on the posterior lateral carinae which is more intense; intercarinal surface with dense and well-defined granules. Pedipalps moderately elongated; hand evenly oval and moderately incrassate. Basal plate of pectines in males is rectangular with the anterior notch V-shaped, anterior margin slightly concave and lobulated, and posterior margin straight, in females the anterior margin is only slightly notched medially and with posterior margin rounded. Pectinal tooth counts 24–26 (mode 25; $n = 14$ in males) vs. 22–25 (mode 23; $n = 14$) in females. Metasoma with dorsolateral, lateral, supramedian and inframedian carinae well developed and serrated; vesicle slightly elongated. Sexual dimorphism evident, females with pedipalps shorter, less slender and more strongly carinate, bulkier hand, metasoma more strongly carinate and with shorter segment V, telson vesicle shorter and rounder, with a stronger subaculear tubercle.

Description of the holotype male (CNAN-T0874)

Coloration. A typical “striped scorpion”, basically yellow, paler ventrally (Fig. 1). Anterior median area of the carapace is heavily pigmented, except for the median furrow and 2 lateral patches that extend from the sides of ocular tubercle through the lateral eyes (Fig. 2a). Posterior median area is slightly pigmented on both sides of the median furrow and darker on posterior lateral carinae. Median furrow immaculate, connected to a pale transverse area from posterior margin through median lateral carinae. Median eyes surrounded by a pattern of subtle spots,

with a heavily pigmented margin. Lateral margins pale immaculate. The area around lateral eyes is very dark, with a pigmented stripe remarked by pale stripes on each side; the pigmented stripe becomes wider toward its posterior median part (Fig. 2a). Ocular tubercle intensely infuscate (Fig. 2a). Pedipalp: femur diffusely infuscate dorsally, becoming darker medially and distally (Fig. 2g). Patella diffusely infuscate dorsally, darker over carinae (Fig. 2h); chelae slightly darker but without defined pattern, except for heavily infuscate carinae (Fig. 2i and j). Legs: irregularly pigmented, including femur, patella and tibiae (Fig. 3e–g). Legs I and II darker on distal area of patella near the articulation with tibiae and diffusely pigmented to immaculate on the rest. Femur, patella and tibiae of legs III–IV darker and becoming weaker on metatarsus (Fig. 3a and b). Mesosoma: dorsally with 2 longitudinal blackish stripes, separated by a slightly wider pale stripe. Each dark stripe is composed of a well-defined, large and concave spot over the postergite, which gradually becomes diffuse as a transversely oriented reticulate pattern through the pretergite, where it then fuses into another smaller, convex spot located just on the edge of tergites I–VI; the dark stripes gradually become diffuse also through tergite VII (Fig. 2c and e). Median longitudinal carena pigmented on all tergites (Fig. 2c). The blotches of the mesosomal dark bands consist of large spots in the postergite, concave toward the pretergite, which has a smaller convex spot. Both spots are interconnected with reticulated pigmentation. On pretergites II–III, every blackish spot looks like a horizontal stripe slightly inclined to the center of the tergite (Fig. 2c) and becomes somewhat crescent-shaped on postergite VII (Fig. 2c and e). Pigmented spots are surrounded by small to medium sized dots (Fig. 2c and e). Sternite VII slightly pigmented on median carinae (Fig. 2f). Metasoma:

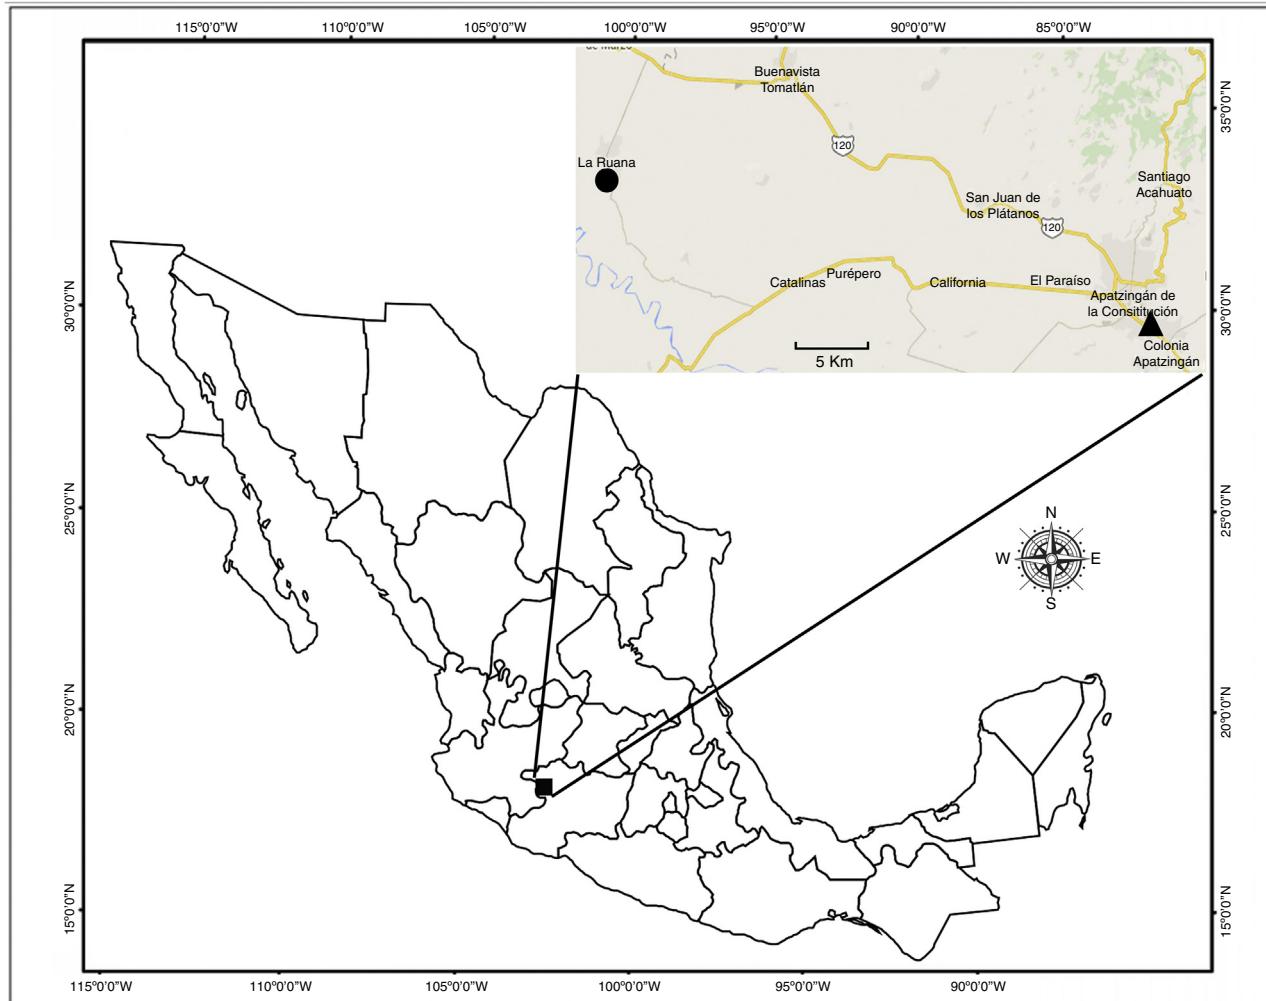

Figure 5. Known geographical distribution of *Centruroides ruana* sp. nov.: type-locality (●) and Apatzingán (△), Michoacán, Mexico.

Modified from Google Maps.

dorsally immaculate, ventrally heavily infuscate over ventrolateral and ventral submedian carinae on I–IV and diffusely spotted on space between ventral submedian and ventrolateral carinae on segments I–III, weaker on IV, and immaculate on V (Figs. 3d and 6.11). Vesicle ochre-yellow; dorsally immaculate; ventrally and laterally with 1 median and 2 lateral infuscate stripes, separated by thin immaculate bands distally to the area around the subaculear tubercle, where spotted pattern becomes diffuse and with yellowish dots (Fig. 3e–g). Aculeus infuscate throughout, with distal half conspicuously darkened.

Carapace. Anterior margin concave, with weakly crenulate edge. Lateral areas feebly granulose to smooth, margins weakly crenulate (Fig. 2a and b). Ocular tubercle smooth, surrounded by small to medium-sized granules on pigmented areas, more developed behind median and lateral eyes (Fig. 2b). Posterior margin straight, with a shallow median indentation or notch, laterally with medium-sized granules (Fig. 2a and b).

Pedipalps. Moderately elongated (length/width ratio of femur and patella = 0.92). All carinae weakly to moderately granulose

(Fig. 2g–j). Intercarinal spaces finely granulose on femur and patella coriaceous on chela (Fig. 2g–j). Chela of pedipalps are granular with well-defined granules. Hand evenly oval and moderately incrassate (width hand/width patella ratio = 1.09; length/width hand ratio = 2.16) (for measurements see Table 2) (Fig. 2i and j). Digital carena moderate and smooth (Fig. 2i); ventroexternal and ventrointernal carinae strong and smooth (Fig. 2j). Fingers long, slender and evenly curved (Fig. 2i and j), with 8 principal rows of denticles flanked by supernumerary denticles on each side, and with an apical subrow of 5 denticles.

Mesosoma. Tergites with strong median longitudinal carinae (Fig. 2d); submedian and lateral carinae on VII strong and serrate (Fig. 2e and f). All pigmented areas are covered by small to medium-sized granules, as in carapace (Fig. 2c and d). Sternite VII with media carinae slightly developed but complete (Fig. 2f).

Pectines. Tooth count 24/24. Basal plate of pectines in males is rectangular with the anterior notch V-shaped, anterior margin slightly concave and lobulated, and posterior margin straight (Table 2; Fig. 3c).

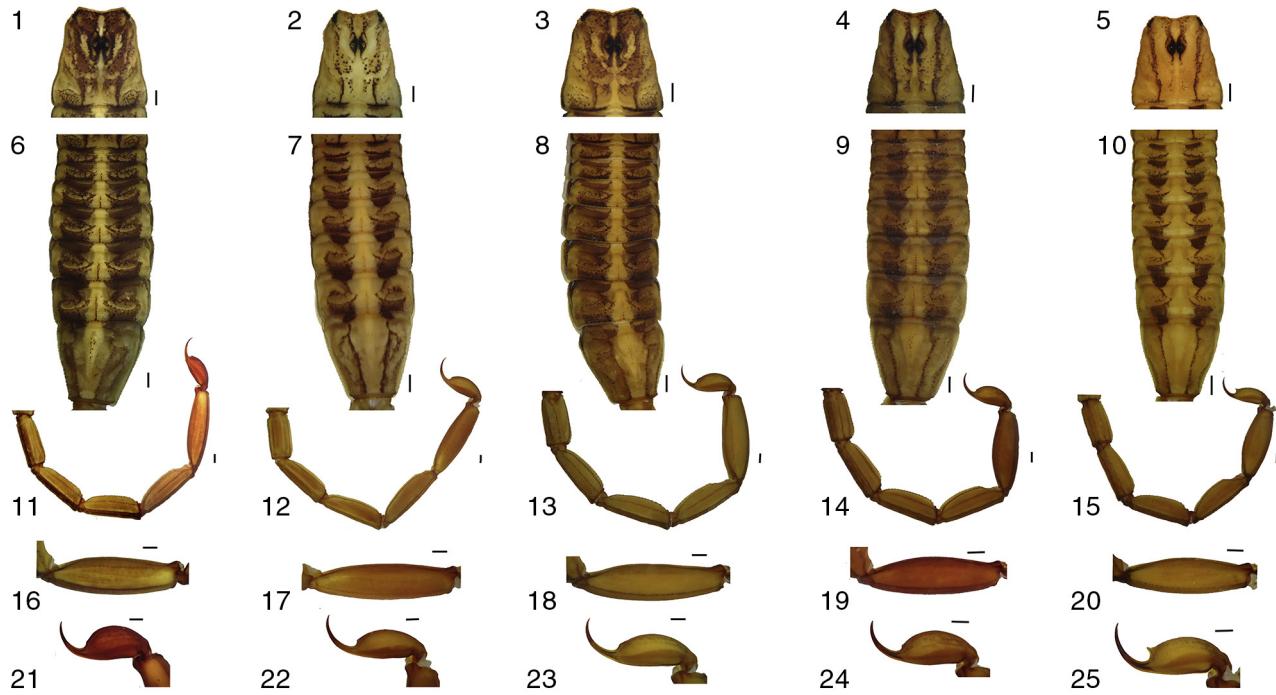

Figure 6. Morphological comparison between: (1), *Centruroides ruana* sp. nov.; (2), *C. balsasensis*; (3), *C. infamatus*; (4), *C. limpidus*, and (5), *C. tecomanus*. (a) pigmentation on the carapace; (b) pigmentation of mesosoma; (c) metasoma, lateral; (d) metasomal segment V, and (e) vesicle and subaculear tubercle. Bars = 1 mm.

Metasoma. Moderately elongated and not incrassate distally (Figs. 3d and 6.11). Segments I–IV with the following carination: dorsal laterals, lateral supramedians and lateral inframedians (on I only) well developed, denticulate, the dorsal lateral carinae become gradually stronger distally on each segment; ventral laterals and ventral submedians well developed, finely serrate, but becoming progressively weaker toward segment IV (Fig. 6.11). Segment V rounded in cross-section, almost entirely acarinate except for subtle vestiges of ventral lateral and ventral median carinae. Intercarinal spaces coriaceous, with vestiges of minute granules on I. Dorsal median furrow undefined on I–II, wide and shallow on III–IV, narrow and shallow on V (Figs. 3d and 6.11, 6.16).

Telson. Vesicle slightly elongated (length/width ratio = 1.90, depth/width ratio = 1.0) and coriaceous, with ventromedian carinae vestigial but progressively stronger distally to the subaculear

tubercle, which is very small, widely conical and somewhat distant from the base of aculeus, which is shorter than vesicle and moderately curved (Figs. 3e–g and 6.21).

Female description and comparison with males. Sexual dimorphism is very well marked (Fig. 1). Females differ from males as follows: color pattern both darker and more contrasting. Tergite VII remarkably wider, with anterior margin concave and pale immaculate (Figs. 1 and 4a). Pedipalps shorter, less slender and more strongly carinate, with bulkier hand with length/width ratio 1.88 ± 0.20 in females ($n=7$) vs. 2.20 ± 0.12 in males ($n=7$) (Figs. 1, 2i, j and 4b, c). Pectines comparatively smaller, with lower tooth counts: 22–25 ($n=14$), mode 23 in females vs. 24–26, mode 25 in males ($n=14$); basal plate with anterior margin almost straight, but posterior margin widely convex (Figs. 3c, 4d and 7). Metasoma shorter and more strongly carinate; segment V length/width ratio 2.48 ± 0.14 in females ($n=7$)

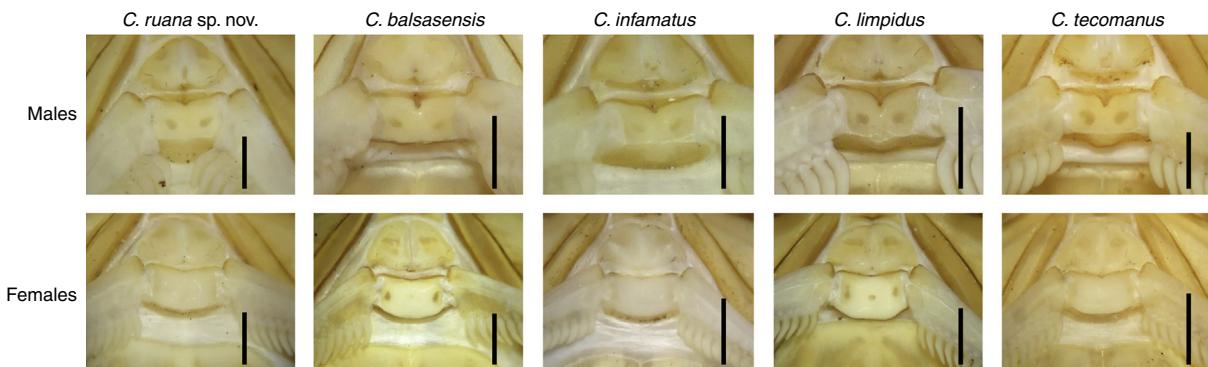

Figure 7. Comparison of pectinal plates of males and females of *Centruroides ruana* sp. nov. *C. balsasensis*, *C. infamatus*, *C. limpidus* and *C. tecomanus*. Bars = 1 mm.

Table 4

Matrix with fourteen variables useful to distinguish females of *Centruroides ruana* sp. nov. from of closely related *Centruroides* or those in the same geographic region.

Females Variable	Mean (\pm SD)						
	<i>C. ruana</i> sp. nov.	<i>C. infamatus</i>	<i>C. balsasensis</i>	<i>C. limpidus</i>	<i>C. tecomanus</i>	Value X^2	Prob.
Pectinal tooth count	22–25 (mode = 23)	20–24 (mode = 21)	25–28 (mode = 25)	20–23 (mode = 22)	20–24 (mode = 21)		
Metasomal segment V/III length ratio	1.24 (\pm 0.03)A	1.25 (\pm 0.03)A	1.17 (\pm 0.03)B	1.17 (\pm 0.01)B	1.16 (\pm 0.02)B	22.2264	0.0002

Pedipalp fixed finger/pedipalp hand length ratio	1.21 (\pm 0.05)A	1.21 (\pm 0.05)A	0.60 (\pm 0.02)B	0.59 (\pm 0.01)BC	0.56 (\pm 0.04)C	24.7901	<0.0001

vs. 3.46 ± 0.29 in males ($n=7$) (Figs. 1, 3d, 4e and 6.11). Telson vesicle shorter and rounder: length/width ratio 1.62 ± 0.02 in females ($n=7$) vs. 2.02 ± 0.04 ($n=7$) in males; subaculear tubercle stronger, aculeus longer, sharper and shallowly curved (Figs. 3e–g and 4f).

Variation. Base color varies from yellow to ochre in both sexes (Fig. 1). Spotted pattern of juvenile instars is both darker and denser, especially on pedipalps; some juveniles also have lateral and ventral surfaces of metasoma very intensely spotted. The subaculear tubercle is vestigial in some adult females, but it is strong, slender and somewhat spinoid in all juveniles.

C. ruana sp. nov. are scorpions of medium to moderately large adult size for the genus, total body length (including telson) 63.0–70.7 (66.8 \pm 1.5, $n=7$) in males, 59.1–62.0 (60.8 \pm 1.0, $n=7$) in females. Carapace length of 5.7–6.4 (6.0 \pm 0.4, $n=7$) in males, 6.1–6.5 (6.3 \pm 0.3, $n=7$) in females. Pedipalps longer and more slender than similar species (length femur and patella: 5.9–6.6 (6.2 \pm 0.4, $n=7$), 6.4–7.2 (6.8 \pm 0.4, $n=7$) in males and 5.4–6.0 (5.7 \pm 0.3, $n=7$), 6.1–6.8 (6.4 \pm 0.4, $n=7$) in females, respectively. Hand relatively longer in females (fixed finger/hand length ratio: 1.1–1.3 [1.2 \pm 0.1, $n=7$] in males, 1.4–1.5 [1.2 \pm 0.03, $n=7$] in females). Movable finger/hand length ratio: 1.1–1.3 (1.2 \pm 0.2, $n=7$) in males, 1.4–1.5 (1.4 \pm 0.03, $n=7$) in females. Basal plate of pectines width/length ratio: 1.5–2.0

(1.7 \pm 1.3, $n=7$) in males, 1.8–2.0 (1.9 \pm 0.08, $n=7$) in females. Total length/metasoma length ratio: 1.78–1.83 (1.8 \pm 0.02, $n=7$) in males, 2.05–2.17 (2.1 \pm 0.05, $n=7$) in females. Number of pectinal teeth is 24–26 (mode = 25; $n=14$) in males and 22–25 (mode = 23; $n=14$) in females.

Taxonomic summary

Type data. Adult male holotype (CNAN-T0874), 1 adult male and 2 adult female paratypes (CNAN-T0875), 6 adult male and 6 adult female paratypes (CAFBUM 2015-0503), all with the following data: Mexico: Michoacán: Buenavista Municipality: Felipe Carrillo Puerto (= La Ruana), Ejido “Santa Rita”, 19.1224°N, 102.7117°W; 7.III.2013; coll. L. Gaona E.

Other material examined

Two adult males and 4 adult females (CAFBUM) with the same data as the types, except collected on 6.XII.2014. One adult female (CAFBUM) from Michoacán: Apatzingán de la Constitución Municipality: Las Colonias: Cenobio Moreno; 19.0933°N, 102.5014°W; 1.VI.2012; coll. J. Ponce, A. Quijano, L. Echeverría. One adult female (CAFBUM) from Michoacán: Apatzingán de la Constitución Municipality: Panteón Municipal; 19.0731°N, 102.3692°W; 2.XI.2013; coll. J. Baldazo.

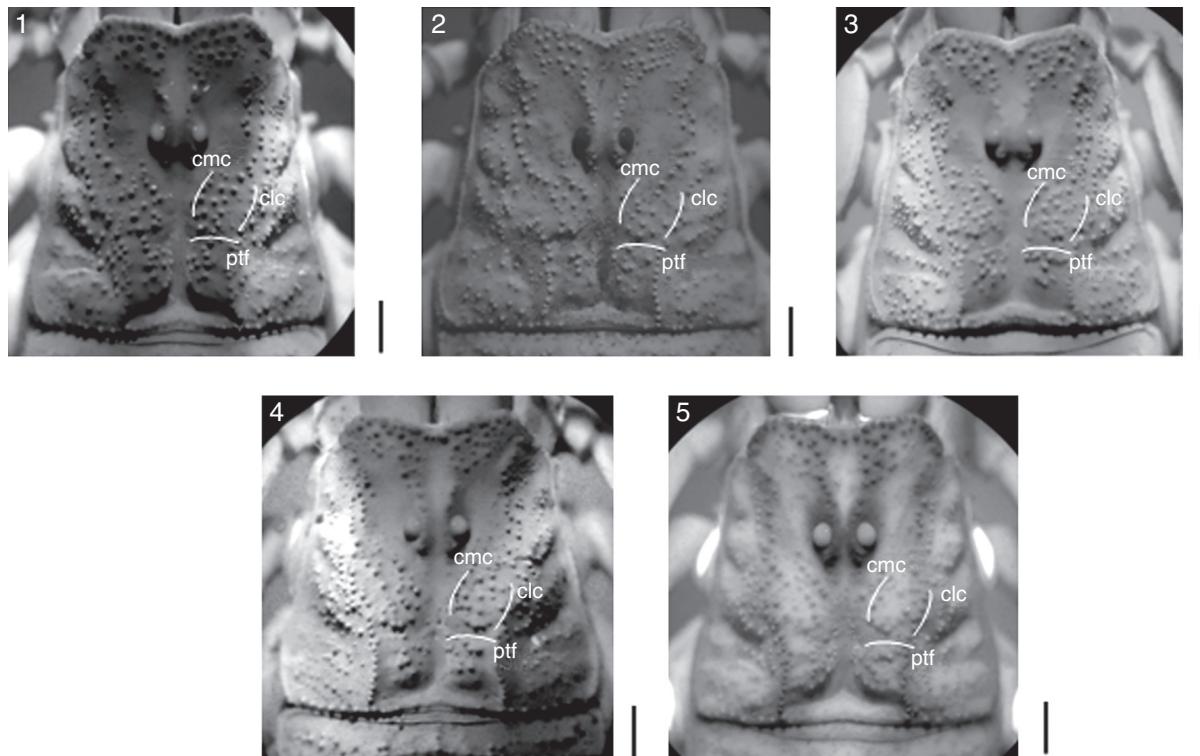

Figure 8. Granulation comparison of carapace between: (1) *Centruroides ruana* sp. nov.; (2) *C. balsasensis*; (3) *C. infamatus*; (4) *C. limpidus*, and (5) *C. tecomanus*. Central median carinae (cmc), central lateral carinae (clc), and posterior transverse furrow (ptf). Bars = 1 mm.

Etymology

The specific epithet is an indeclinable noun in apposition, taken directly from the unofficial but better-known name of the type locality: Felipe Carrillo Puerto (= La Ruana).

Distribution

Only known from 2 nearby localities of the lowland Balsas Basin, in west-central Michoacán (Fig. 4). Both localities are in the Apatzingán Valley (Fig. 5).

Remarks

The new species is similar in size and coloration to *Centruroides infamatus* (Fig. 6), and both taxa are also geographically close. The latter can be distinguished by the less slender pedipalps, with femur, patella and chela shorter; hand of pedipalp slightly less elongated; metasoma and telson longer (Table 2). Also, metasoma with dorsal lateral, lateral supramedian, and lateral inframedian carinae less developed and granular to crenulated except the dorsal laterals, which are finely serrated and even denticulate (Fig. 6.11, 6.14). The basal plate of pectines in males of *C. infamatus* with the anteromedian notch shallow and the anterior margin not lobulated, in females with the anterior margin concave but not notched and posterior margin clearly recurved (Fig. 7).

Another species that is morphologically similar and found in the same geographic region is *C. balsasensis* (Fig. 6), which can be differentiated from *C. ruana* sp. nov. by the coloration paler and less densely patterned, the color pattern on carapace and

tergites (Fig. 6), and the carapace with anterior margin noticeably notched, convex, with granules that are denser on the median part. General habitus of *C. balsasensis* slightly less slender, including pedipalps with more robust chelae (obvious in the fingers/manus length ratio) (Tables 3 and 4); basal pectinal plate of males of *C. balsasensis* with anterior margin almost straight and not lobulated; in females the anterior margin is clearly concave and the posterior margin is strongly convex. Males of *C. balsasensis* with subaculear tubercle markedly stronger (Fig. 7).

Centruroides limpidus is more distantly related to *C. ruana* sp. nov. based on morphological criteria, but both species are sympatric in the Felipe Carrillo Puerto area. Although *C. limpidus* is present in very low abundance here, it is easy to recognize by the carapace color pattern, which has 2 pairs of thin, longitudinal, sub parallel blackish stripes: 1 lateral across the entire carapace (Fig. 6.21, 6.24), and 1 submedian that extends shortly behind the ocular tubercle (Fig. 6.1, 6.2), leaving most part of the surface without pigment. Other differences are morphometric features (for measurements see Tables 3 and 4).

Centruroides tecomanus is another species that could be confused with the new species herein described (Figs. 6 and 7), owing to its general appearance; however, in addition to the morphometric differences (Tables 3 and 4), the coastal distribution of this species; the constant color pattern of its carapace, always with 4 thin and well defined dark lines (Fig. 6.1, 6.5); and the subaculear tubercle well developed and generally with its point oriented toward the point of aculeus (Ponce-Saavedra et al., 2009) (Fig. 6.21, 6.25) are enough to distinguish this species from the newly described one.

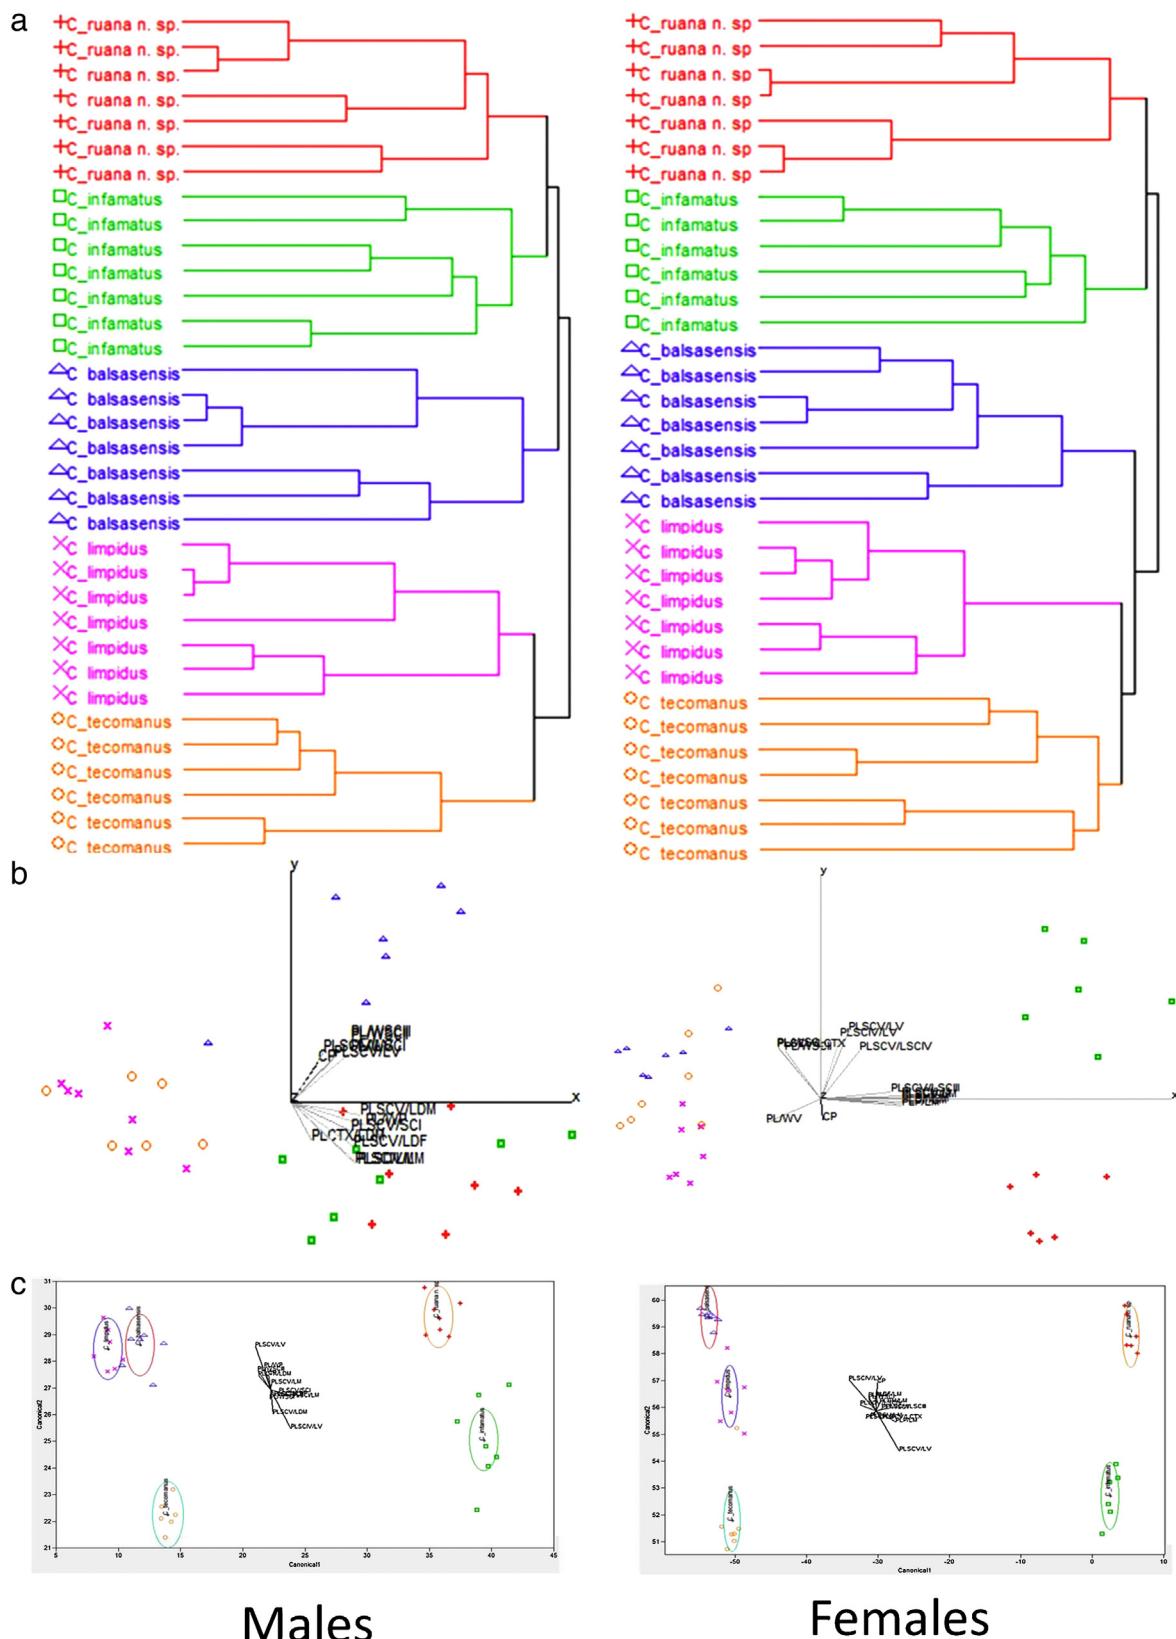

Figure 9. (a) clustering plots obtained with Ward's method and standardized data; (b) ordination graphics of 2 first principal components of PCA, and (c) graphics obtained from canonical discriminant analysis. All analyses were made with 13 variables in females and 14 in males. *Centruroides ruana* sp. nov. (plus symbol), *C. infamatus* (square), *C. balsasensis* (triangle), *C. limpidus* (letter X), *C. tecomanus* (circle).

Additionally we made a comparison of granulation pattern of the carapace of *C. ruana* sp. nov., *C. balsasensis*, *C. infamatus*, *C. limpidus*, and *C. tecomanus* using images in UV light. Differences in the patterns of granulation of central median carinae (cmc) and central lateral carinae (clc) as well as in the granulation located above the posterior transverse furrow (ptf) can be appreciated between species (Fig. 8).

Morphometric analysis

A morphometric statistical analysis was conducted in order to reinforce the diagnostic comparison between *C. ruana* sp. nov., *C. balsasensis*, *C. infamatus*, *C. limpidus*, and *C. tecomanus*. As a whole, 54 variables were included: 28 measurements, 25 derived proportional ratios and a meristic count. Matrices were constructed using the following labels for each taxon: C_ruana, C_balsasensis, C_infamatus, C_limpidus, and C_tecomanus. A Cluster Analysis (CA) was performed using Euclidean distances, standardized data and Ward's Minimum Variance Method followed by a Principal Component Analysis (PCA). The results revealed that specimens previously assigned to a particular taxon, consistently clustered together and isolated from others, forming groups of defined species (Fig. 9a).

In order to reduce the number of variables supporting the species distinction and to discard any potential effect of size among the 3 taxa (a clean-up process), all matrices were depurated by eliminating those variables found to be highly correlated or with little information. The former are simple redundant, while the latter represent variation which is very poorly explained through the PCA. As outcomes, a thirteen variable matrix was obtained for males and another with fourteen for females (Tables 3 and 4).

Using these variables and running separate analyses for both males and females, a second CA was calculated, and again, specimens of each previously identified taxon clustered together and were separated from all other species (Fig. 9a). A subsequent PCA applied to these matrices yielded 85.67% and 87.55% of explained variation in 3 principal components for both males and females, respectively (Fig. 9b). Further, a canonical discriminant analysis (CDA) demonstrated that the morphometric distinction of all species is adequate (Fig. 9c): tests such as Wilks' Lambda, Pillai's Trace, Hotelling-Lawley and Roy's Max Root, all proved significant ($p < 0.05$) and yielded null misclassifications. In males (Table 3), thirteen variables were found to present univariate significant statistical difference ($p < 0.05$). In females (Table 4), the number of such variables was fourteen ($p < 0.05$).

The morphologic and morphometric data support *C. ruana* sp. nov. as a valid species, clearly distinct from the morphologically similar *C. balsasensis* and *C. infamatus* and from *C. limpidus*, which is the species found closest geographically. The difference with *C. tecomanus* was also clear. The overall resemblance in the habitus among *C. limpidus* and *C. balsasensis* and *C. ruana* makes it very likely that this new species is actually more widespread across the Balsas Basin, but has been misidentified in collections.

Acknowledgements

This paper forms part of the first author's PhD thesis, a study that was funded through a grant from the Consejo Nacional de Ciencia y Tecnología, Mexico. We are grateful to the Coordinación de la Investigación Científica of Universidad Michoacana de San Nicolás de Hidalgo for the support for field work; to Lizbeth Gaona Escamilla and M.C. José Guadalupe Baldazo Monsiváiz for collecting and donating most specimens of the new species; to Dr. Rolando Teruel for the thorough review of the manuscript, the English translation of the final draft, and his valuable and helpful comments. We are grateful to Dr. Oscar F. Francke for his valuable comments and Dr. Robert W. Jones for the review of the English final manuscript.
